

Getting started with Machine Learning (ML) and Support Vector Classifiers (SVC) - A systematic step-by-step approach

Dipl.-Ing. Björn Kasper (kasper.bjoern@bgetem.de)

Test and Certification Body for Electrical Engineering at BG ETEM

August 7, 2022

Anyone who wants to seriously deal with the hypothetical topic of our time “Artificial Intelligence (AI)” or “Machine Learning (ML)” cannot avoid dealing with the basic ML algorithms, corresponding software tools, libraries and programming systems. However, someone who opens the door for the first time to this equally very exciting as well as arbitrarily complex and, at first glance, confusing world will very quickly be overwhelmed. Here, it is a good idea to consult introductory and systematic tutorials. Therefore, this Getting Started tutorial systematically demonstrates the typical ML work process step-by-step using the very powerful and performant “Support Vector Classifier (SVC)” and the widely known and very beginner-friendly “Iris Dataset”. Furthermore, the selection of the “correct” SVC kernel and its parameters are described and their effect on the classification result is shown.

1 Introduction

1.1 English introduction

In the **digitised work environment**, there is an increasing demand for **Work equipment** to be able to adapt independently and in a task-related manner to changing work situations. This **situational adaptivity** can often only be realised through the use of **Artificial Intelligence (AI)** or **Machine Learning (ML)**, depending on the degree of flexibility. Examples of such AI applications in the world of work can range from comparatively simple **voice assistance systems** (similar, for example, to Siri or Alexa from the private sphere) to partially or even **fully autonomous systems**. Such fully autonomous

systems are, for example, autonomously driving logistics vehicles in larger industrial plants (so-called **driverless transport systems**).

In addition to the many very interesting advantages in terms of economic efficiency, workload reduction, etc., such fully autonomous systems are characterised by a very high level of technical complexity. This concerns both their **operating functions** (e.g. autonomous navigation through complex industrial environments with shared use of the roadways by other human-controlled vehicles) and their **safety functions** (e.g. evaluation of complex, interconnected, mostly imaging safety sensors for monitoring the driving space).

Very high demands are placed on such autonomous systems and the AI algorithms used for them with regard to **functional safety**. However, when assessing their safety, one quickly comes up against clear limits with regard to the **transparency** and **explainability** of the decisions made by AI as well as limits to the **recognition rates** and thus their **reliability**. In particular, the detection rates achievable by AI even under the most convenient conditions very often do not meet the requirements for realising higher safety levels (e.g. Performance Level d (PLd) according to ISO 13849).

An appropriate assessment or even **testing** with regard to the required functional safety according to uniform and ideally standardised criteria has many implications for the future orientation of technical **occupational safety and health (OSH)** in Germany and in Europe. In addition to the currently still very difficult algorithmic evaluability, a significant aspect is that the previous clear separation between **placing on the market law** (see e.g. Machinery Directive) and **occupational health and safety law** (see European Occupational Health and Safety Framework Directive and German Ordinance on Occupational Safety and Health) can no longer be continued in this way. The reason for this is that the **safety-relevant properties** of the autonomous systems will change due to new or **adapted behaviours** learned during operation.

For these reasons, those involved in technical occupational safety and health who will be involved in the testing of work equipment in the future should deal with AI and ML algorithms in depth as early as possible. This is the only way to ensure that the rapid development of adaptive systems capable of learning can be accompanied by OSH and its testing institutes in a constructive, critical and technically appropriate manner. If this is not done, the OSH system will be ruthlessly circumvented or undermined by the economic interests of globally operating software giants. This would have the consequence that serious or fatal occupational accidents are likely to occur due to inadequately designed AI-based work systems.

Anyone seeking a serious technical entrance into the world of **Artificial Intelligence (AI)** or **Machine Learning (ML)** will not be able to avoid dealing with the basic ML algorithms, corresponding software tools, libraries and programming systems.

However, someone who opens the door for the first time to this equally very exciting as well as arbitrarily complex and, at first glance, confusing world will very quickly be overwhelmed. Here, it is a good idea to consult introductory and systematic tutorials.

The aim of this Getting Started tutorial is to systematically demonstrate the typical ML working process step-by-step based on the example of the very powerful and performant **Support Vector Classifier (SVC)**.

This tutorial will be presented as part of a workshop at the DGUV symposium **Artificial Intelligence**, probably in November 2022 in Dresden. The workshop addresses interested ML novices in the technical occupational safety and health of the social accident insurance institutions.

For the target audience in the workshop, the SVC algorithm was intentionally chosen to show that there are many other very powerful and performant ML algorithms apart from the **deep neural networks** that are very present in the media. On the other hand, a necessary and comprehensible introduction to neural networks and the technical background to perceptrons, activation functions etc. for newcomers would not be possible within the time frame given for the workshop.

Furthermore, this tutorial does *not* address the generation or acquisition of ML-ready datasets. Reason for this is that a newcomer to ML will (or should) first try to familiarize himself with ML algorithms, tools, libraries and programming systems. Only then it makes sense to explore one's own environment with respect to ML-suitable applications and to acquire suitable datasets from them.

Therefore, this tutorial demonstrates the usage of selected ML tools in the form of Python libraries as well as the systematic approach to the widely known and very beginner-friendly **Iris dataset**. According to the literature, the Support Vector Classifier is particularly well suited for the classification of the iris dataset in terms of recognition rate and performance. Alternatively, decision tree-based ML algorithms such as the **Random Forests Classifier** could be used.

After the classification of the iris dataset by the SVC initially with standard parameters, the selection of the “correct” SVC kernel with its setting parameters is furthermore described and the effect on the classification result is shown.

1.2 German introduction

Von den **Arbeitsmitteln** in der **digitalisierten Arbeitswelt** wird immer stärker gefordert, dass sie sich selbstständig und aufgabenbezogen an sich ändernde Arbeitssituationen anpassen können. Diese **situative Adaptivität** kann je nach Stärke des Flexibilisierungsgrades oft nur durch Anwendung von **Artificial Intelligence (AI)** oder **Machine Learning (ML)** realisiert werden.

Als Beispiele für solche KI-Anwendungen in der Arbeitswelt können vergleichsweise einfache **Sprachassistentensysteme** (ähnlich z. B. Siri oder Alexa aus dem privaten Umfeld) bis hin zu teil- oder gar **vollautonomen Systemen** genannt werden. Solche vollautonomen Systemen sind beispielsweise autonom fahrende Logistikfahrzeuge in größeren Industrieanlagen (sog. **fahrerlosen Transportsystemen**).

Neben den vielen sehr interessanten Vorteilen bzgl. Wirtschaftlichkeit, Arbeitserleichterung usw. kennzeichnet solche vollautonomen Systeme eine sehr hohe technische Komplexität. Diese betrifft sowohl ihre **Betriebsfunktionen** (z. B. autonome Navigation durch komplexe industrielle Umgebungen bei gemeinsamer Nutzung der Fahrwege durch andere menschlich gesteuerte Fahrzeuge) als auch seiner **Sicherheitsfunktionen** (z. B. Auswertung komplexer, miteinander verknüpfter, meist bildgebender Sicherheitssensorik zur Überwachung des Fahrraums).

An solche autonomen Systeme und die hierfür eingesetzten KI-Algorithmen werden sehr hohe Anforderungen hinsichtlich der **funktionalen Sicherheit** gestellt. Jedoch stößt man bei ihrer sicherheitstechnischen Bewertung heute noch sehr schnell an deutliche Grenzen hinsichtlich der **Transparenz** und **Erklärbarkeit** der durch KI getroffenen Entscheidungen sowie Grenzen der **Erkennungsraten** und damit ihrer **Zuverlässigkeit**. Insbesondere erfüllen die durch KI selbst unter günstigsten Bedingungen erreichbaren Erkennungsraten sehr oft nicht die Anfordererungen, um höhere Safety-Level (z. B. Performance Level d (PLd) nach ISO 13849) zu realisieren.

Eine hinsichtlich der geforderten funktionalen Sicherheit angemessene Bewertung oder gar **Prüfung** nach einheitlichen und idealerweise genormten Maßstäben hat viele Implikationen auf die zukünftige Ausrichtung des **technischen Arbeitsschutzes** in Deutschland und in Europa. Neben der derzeit noch sehr schwierigen algorithmischen Bewertbarkeit ist ein wesentlicher Aspekt, dass die bisherige klare Trennung zwischen **Inverkehrbringensrecht** (siehe z. B. Maschinenrichtlinie) und **betrieblichem Arbeitsschutzrecht** (siehe Arbeitsschutzrahmenrichtlinie und Betriebssicherheitsverordnung) so nicht mehr aufrechterhalten werden kann. Grund hierfür ist, dass sich die **sicherheitsrelevanten Eigenschaften** der autonomen Systeme durch während des Betriebs erlernte, neue oder **angepasste Verhaltensweisen** verändern werden.

Aus diesen Gründen sollten sich insbesondere die zukünftig mit der Prüfung befassten Akteure des technischen Arbeitsschutzes möglichst frühzeitig mit den KI- bzw. ML-Algorithmen vertieft auseinandersetzen. Nur dadurch lässt sich erreichen, dass die stürmische Entwicklung lernfähiger, adaptiver Systeme durch den Arbeitsschutz und deren Prüfinstitute konstruktiv, kritisch und fachlich angemessen begleitet werden kann. Wird dies versäumt, wird das Arbeitsschutzsystem durch die wirtschaftlichen Interessen global agierender Softwaregiganten skrupellos umgangen oder ausgehebelt werden. Dies hätte die Folge, dass schwere oder tödliche Arbeitsunfälle auf Grund unzulänglich gestalteter KI-basierter Arbeitssysteme wahrscheinlich werden.

Wer einen ernsthaften fachlichen Einstieg in die Welt von **Künstlicher Intelligenz (KI)** bzw. **Machine Learning (ML)** sucht, wird nicht umhin kommen, sich mit den grundlegenden ML-Algorithmen, entsprechenden Software-Werkzeugen, Bibliotheken und Programmiersystemen auseinander zu setzen.

Wer jedoch zum ersten Mal die Tür zu dieser ebenso spannenden wie beliebig komplexen und auf den

ersten Blick verwirrenden Welt öffnet, wird sehr schnell überfordert sein. Hier empfiehlt es sich, einführende und systematische Anleitungen zu Rate zu ziehen.

Ziel dieses Getting-Started-Tutorials ist es, den typischen ML-Arbeitsablauf systematisch und Schritt-für-Schritt am Beispiel des sehr leistungsfähigen **Support Vector Classifier (SVC)** zu demonstrieren.

Dieses Tutorial wird im Rahmen eines Workshops auf der DGUV-Fachtagung **Künstliche Intelligenz** voraussichtlich im November 2022 in Dresden vorgestellt. Der Workshop richtet sich an interessierte ML-Neulinge im technischen Arbeitsschutz der gesetzlichen Unfallversicherungsträger.

Für die Zielgruppe des Workshops wurde der SVC-Algorithmus bewusst gewählt, um zu zeigen, dass es neben den **tiefen neuronalen Netzen**, die in den Medien sehr präsent sind, noch viele andere sehr leistungsfähige ML-Algorithmen gibt. Andererseits wäre eine notwendige und verständliche Einführung in neuronale Netze und die technischen Hintergründe zu Perzeptronen, Aktivierungsfunktionen etc. für Neulinge in dem für den Workshop vorgegebenen Zeitrahmen nicht möglich gewesen.

Außerdem befasst sich dieses Tutorial *nicht* mit der Erzeugung oder Akquisition von ML-tauglichen Datensätzen. Der Grund dafür ist, dass ein ML-Neuling zunächst versuchen wird (oder sollte), sich mit den ML-Algorithmen, Werkzeugen, Bibliotheken und Programmiersystemen vertraut zu machen. Erst dann ist es sinnvoll, die eigene Umgebung auf ML-taugliche Anwendungen hin zu untersuchen und daraus geeignete Datensätze zu gewinnen.

Daher demonstriert dieses Tutorial die Verwendung ausgewählter ML-Tools in Form von Python-Bibliotheken sowie die systematische Herangehensweise an den weithin bekannten und sehr einsteigerfreundlichen **Iris-Datensatz**. Laut Fachliteratur ist für die Klassifikation des Iris-Datensatzes der Support Vector Classifier hinsichtlich Erkennungsrate als auch Performanz besonders gut geeignet. Alternativ könnten auch entscheidungsbaum-basierte ML-Algorithmen wie z. B. der **Random-forests-Klassifikator** eingesetzt werden.

Nach der Klassifikation des Iris-Datensatzes durch den SVC zunächst mit Standard-Parametern wird darüber hinaus die Auswahl des "richtigen" SVC-Kernels mit seinen Einstellparametern beschrieben und die Auswirkung auf das Klassifikationsergebnis wird gezeigt.

1.3 Steps of the systematic ML process

The following steps of the systematic ML process are covered in the next main sections:

- STEP 0: Get the dataset
- STEP 1: Exploring the dataset
- STEP 2: Prepare the dataset
- STEP 3: Classify by support vector classifier - SVC
- STEP 4: Evaluate the classification results - metrics
- STEP 5: Select SVC kernel and vary parameters

2 Load globally used libraries and set plot parameters

```
[1]: import time

from IPython.display import HTML

import pandas as pd
import matplotlib.pyplot as plt
from sklearn import svm, metrics
import seaborn as sns
%matplotlib inline
```

3 STEP 0: Get the dataset

Since this is intended to be an introduction to the world of machine learning (ML), this step does NOT deal with the design of an application suitable for ML and the acquisition of valid measurement data.

In order to get to know the typical work steps and ML tools, the use of **well-known and well-researched data sets** is clearly **recommended**.

In the further course, the famous [Iris flower data sets](#) will be used. It can be downloaded on [Iris Flower Dataset | Kaggle](#). Furthermore, the dataset is included in Python in the machine learning package [Scikit-learn](#), so that users can access it without having to find a special source for it.

```
[2]: # import some data to play with
irisdata_df = pd.read_csv('./datasets/IRIS_flower_dataset_kaggle.csv')
```

4 STEP 1: Exploring the dataset

4.1 Goals of exploration

The objectives of the exploration of the dataset are as follows:

1. Clarify the **origins history**:
 - Where did the data come from? => Contact persons and licensing permissions?
 - Who obtained the data and with which (measurement) methods? => Did systematic errors occur during the acquisition?
 - What were they originally intended for? => Can they be used for my application?
2. Overview of the internal **structure and organisation** of the data:
 - Which columns are there? => With which methods can they be read in (e.g. import of CSV files)?
 - What do they contain for (physical) measured variables? => Which technical or physical correlations exist?
 - Which data formats or types are there? => Do they have to be converted?
 - In which value ranges do the measurement data vary? => Are normalizations necessary?
3. Identify **anomalies** in the data sets:
 - Do the data have **gaps or duplicates**? => Does the data set needs to be cleaned?
 - Are there obvious erroneous entries or measurement outliers? => Does (statistical) filtering have to be carried out?
4. Avoidance of **tendencies due to bias**:
 - Are all possible classes included in the dataset and equally distributed? => Does the data set need to be enriched with additional data for balance?
5. Find a first rough **idea of which correlations** could be in the data set

4.2 Clarify the origins history

The **Iris flower data sets** is a multivariate data set introduced by the British statistician and biologist *Ronald Fisher* in his paper “The use of multiple measurements in taxonomic problems as an example of linear discriminant analysis” (1936). It is sometimes called *Anderson’s Iris data set* because Edgar Anderson collected the data to quantify the morphologic variation of Iris flowers of three related species (source: [Iris flower data set](#)).

The dataset is published in Public Domain with a [CC0-License](#).

This dataset became a typical test case for many statistical classification techniques in machine learning such as **support vector machines**.

[..] measurements of the flowers of fifty plants each of the two species *Iris setosa* and *I. versicolor*, found **growing together in the same colony** and measured by Dr E. Anderson [..] (source: R. A. Fisher (1936). “The use of multiple measurements in taxonomic problems”. [Annals of Eugenics](#))

[..] *Iris virginica*, differs from the two other samples in **not being taken from the same natural colony** [..] (source: ibidem)

4.3 Overview of the internal structure and organisation of the data

The data set consists of 50 samples from each of three species of Iris (*Iris setosa*, *Iris virginica* and *Iris versicolor*), so there are 150 total samples. Four features were measured from each sample: the length and the width of the **sepals** and **petals**, in centimetres.

Here is a principle illustration of a flower with sepal and petal:

Figure 1: Principle illustration of a flower with sepal and petal (source: [Mature_flower_diagram.svg](#), license: public domain)

Here are pictures of the three different Iris species (*Iris setosa*, *Iris virginica* and *Iris versicolor*). Given the dimensions of the flower, it will be possible to predict the class of the flower.

Figure 2: left: *Iris setosa* (source: [Irissetosa1.jpg](#), license: public domain); middle: *Iris versicolor* (source: [Iris_versicolor_3.jpg](#), license: CC-SA 3.0); right: *Iris virginica* (source: [Iris_virginica.jpg](#), license: CC-SA 2.0)

4.3.1 Inspect structure of dataframe

Print first or last 5 rows of dataframe:

```
[3]: irisdata_df.head()
```

```
[3]:      sepal_length  sepal_width  petal_length  petal_width      species
0           5.1           3.5           1.4           0.2  Iris-setosa
1           4.9           3.0           1.4           0.2  Iris-setosa
2           4.7           3.2           1.3           0.2  Iris-setosa
3           4.6           3.1           1.5           0.2  Iris-setosa
4           5.0           3.6           1.4           0.2  Iris-setosa
```

```
[4]: irisdata_df.tail()
```

```
[4]:      sepal_length  sepal_width  petal_length  petal_width      species
145           6.7           3.0           5.2           2.3  Iris-virginica
146           6.3           2.5           5.0           1.9  Iris-virginica
147           6.5           3.0           5.2           2.0  Iris-virginica
148           6.2           3.4           5.4           2.3  Iris-virginica
149           5.9           3.0           5.1           1.8  Iris-virginica
```

While printing a dataframe - only an abbreviated view of the dataframe is shown :(
Default setting in the pandas library makes it to display only 5 lines from head and from tail.

```
[5]: irisdata_df
```

```
[5]:      sepal_length  sepal_width  petal_length  petal_width      species
0           5.1           3.5           1.4           0.2  Iris-setosa
1           4.9           3.0           1.4           0.2  Iris-setosa
2           4.7           3.2           1.3           0.2  Iris-setosa
3           4.6           3.1           1.5           0.2  Iris-setosa
4           5.0           3.6           1.4           0.2  Iris-setosa
..          ...           ...           ...           ...          ...
145          6.7           3.0           5.2           2.3  Iris-virginica
146          6.3           2.5           5.0           1.9  Iris-virginica
147          6.5           3.0           5.2           2.0  Iris-virginica
148          6.2           3.4           5.4           2.3  Iris-virginica
149          5.9           3.0           5.1           1.8  Iris-virginica
```

[150 rows x 5 columns]

To print all rows of a dataframe, the option `display.max_rows` has to set to `None` in pandas:

```
[6]: pd.set_option('display.max_rows', None)
irisdata_df
```

```
[6]:      sepal_length  sepal_width  petal_length  petal_width      species
0           5.1           3.5           1.4           0.2  Iris-setosa
1           4.9           3.0           1.4           0.2  Iris-setosa
2           4.7           3.2           1.3           0.2  Iris-setosa
3           4.6           3.1           1.5           0.2  Iris-setosa
4           5.0           3.6           1.4           0.2  Iris-setosa
5           5.4           3.9           1.7           0.4  Iris-setosa
6           4.6           3.4           1.4           0.3  Iris-setosa
7           5.0           3.4           1.5           0.2  Iris-setosa
8           4.4           2.9           1.4           0.2  Iris-setosa
9           4.9           3.1           1.5           0.1  Iris-setosa
10          5.4           3.7           1.5           0.2  Iris-setosa
11          4.8           3.4           1.6           0.2  Iris-setosa
12          4.8           3.0           1.4           0.1  Iris-setosa
13          4.3           3.0           1.1           0.1  Iris-setosa
14          5.8           4.0           1.2           0.2  Iris-setosa
15          5.7           4.4           1.5           0.4  Iris-setosa
```

149	5.9	3.0	5.1	1.8	Iris-virginica

4.3.2 Get data types

```
[7]: irisdata_df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 150 entries, 0 to 149
Data columns (total 5 columns):
#   Column          Non-Null Count  Dtype
---  -
0   sepal_length    150 non-null   float64
1   sepal_width     150 non-null   float64
2   petal_length    150 non-null   float64
3   petal_width     150 non-null   float64
4   species         150 non-null   object
dtypes: float64(4), object(1)
memory usage: 6.0+ KB
```

```
[8]: irisdata_df.describe()
```

```
[8]:
```

	sepal_length	sepal_width	petal_length	petal_width
count	150.000000	150.000000	150.000000	150.000000
mean	5.843333	3.054000	3.758667	1.198667
std	0.828066	0.433594	1.764420	0.763161
min	4.300000	2.000000	1.000000	0.100000
25%	5.100000	2.800000	1.600000	0.300000
50%	5.800000	3.000000	4.350000	1.300000
75%	6.400000	3.300000	5.100000	1.800000
max	7.900000	4.400000	6.900000	2.500000

4.3.3 Get data ranges with Boxplots

Boxplots can be used to explore the data ranges in the dataset. These also provide information about outliers.

```
[9]: sns.set_context("notebook", font_scale=1.3, rc={"lines.linewidth": 2.0})
sns.set_style("whitegrid")
#sns.set_style("white")

fig, axs = plt.subplots(2, 2, figsize=(12, 10))

fn = ['sepal_length', 'sepal_width', 'petal_length', 'petal_width']
cn = ['Iris-setosa', 'Iris-versicolor', 'Iris-virginica']
box1 = sns.boxplot(x = 'species', y = 'sepal_length',
                    data = irisdata_df, order = cn, ax = axs[0,0])
box2 = sns.boxplot(x = 'species', y = 'sepal_width',
                    data = irisdata_df, order = cn, ax = axs[0,1])
box3 = sns.boxplot(x = 'species', y = 'petal_length',
                    data = irisdata_df, order = cn, ax = axs[1,0])
box4 = sns.boxplot(x = 'species', y = 'petal_width',
                    data = irisdata_df, order = cn, ax = axs[1,1])

# add some spacing between subplots
fig.tight_layout(pad=2.0)

plt.show()
```

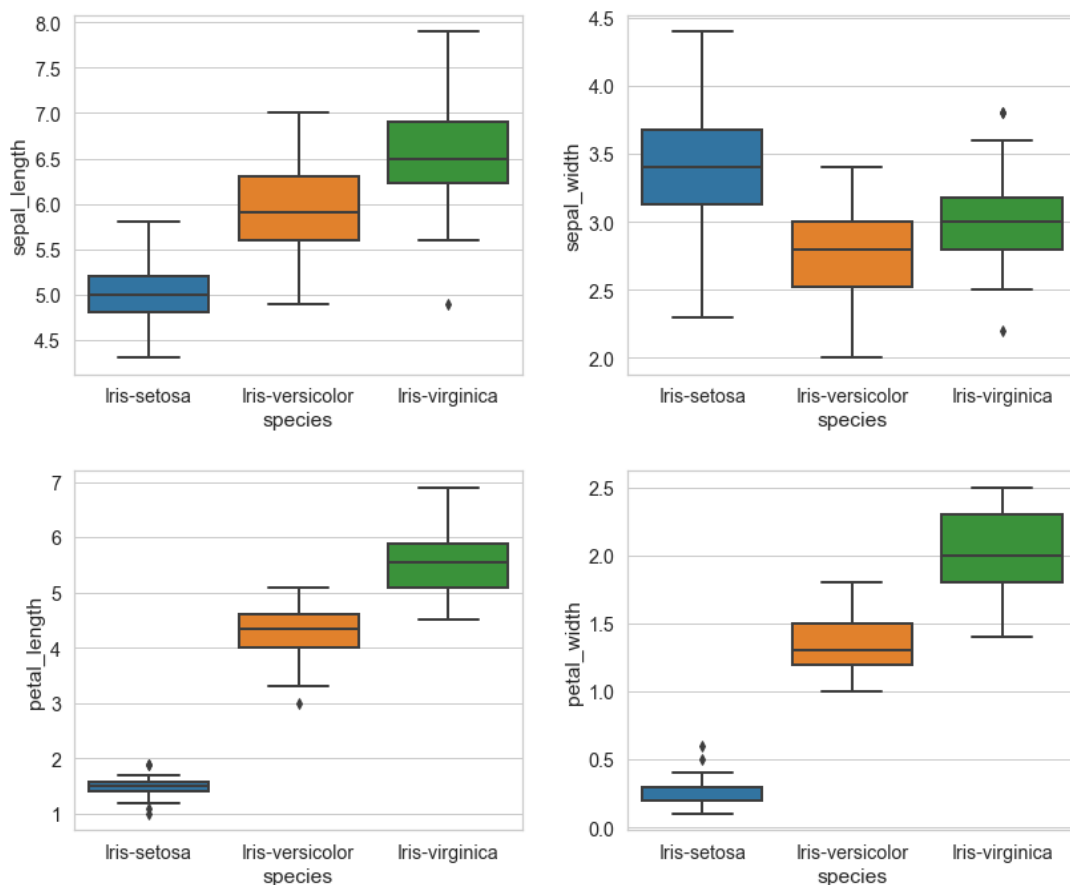

Figure 3: Boxplots used to explore the data ranges in the Iris dataset

4.4 Identify anomalies in the data sets

4.4.1 Find gaps in dataset

This section was inspired by [Working with Missing Data in Pandas](#).

Checking for missing values using `isnull()` In order to check for missing values in Pandas DataFrame, we use the function `isnull()`. This function returns a dataframe of Boolean values which are True for NaN values.

```
[10]: pd.set_option('display.max_rows', 40)
      pd.set_option('display.min_rows', 30)
```

```
[11]: irisdata_df.isnull()
```

```
[11]:      sepal_length  sepal_width  petal_length  petal_width  species
0             False           False           False           False  False
1             False           False           False           False  False
2             False           False           False           False  False
3             False           False           False           False  False
4             False           False           False           False  False
5             False           False           False           False  False
6             False           False           False           False  False
7             False           False           False           False  False
8             False           False           False           False  False
9             False           False           False           False  False
10            False           False           False           False  False
11            False           False           False           False  False
12            False           False           False           False  False
13            False           False           False           False  False
14            False           False           False           False  False
..            ...             ...             ...             ...      ...
135           False           False           False           False  False
136           False           False           False           False  False
137           False           False           False           False  False
138           False           False           False           False  False
139           False           False           False           False  False
140           False           False           False           False  False
141           False           False           False           False  False
142           False           False           False           False  False
143           False           False           False           False  False
144           False           False           False           False  False
145           False           False           False           False  False
146           False           False           False           False  False
147           False           False           False           False  False
148           False           False           False           False  False
149           False           False           False           False  False
```

[150 rows x 5 columns]

Show only the gaps:

```
[12]: irisdata_df_gaps = irisdata_df[irisdata_df.isnull().any(axis=1)]
      irisdata_df_gaps
```

```
[12]: Empty DataFrame
      Columns: [sepal_length, sepal_width, petal_length, petal_width, species]
      Index: []
```

Fine - this dataset seems to be complete :)

So let's look for something else for exercise: [employees.csv](#)

```
[13]: # import data to dataframe from csv file
employees_df = pd.read_csv("../datasets/employees_edit.csv")

employees_df
```

```

[237 rows x 8 columns]

Fill the missing values with fillna() Now we are going to fill all the null (NaN) values in Gender column with “No Gender”.

Attention: We are doing that directly in this dataframe with `inplace = True` - we don't make a deep copy!

```

[15]: # filling a null values using fillna()
employees_df["Gender"].fillna("No Gender", inplace = True)
employees_df

```

```

[1004 rows x 8 columns]

Dropping missing values using dropna() In order to drop null values from a dataframe, we use dropna() function. This function drops rows or columns of datasets with NaN values in different ways.

Default is to drop rows with at least 1 null value (NaN). Giving the parameter `how = 'all'` the function drops rows with all data missing or contain null values (NaN).

```
[16]: # making a new dataframe with dropped NaN values
employees_df_dropped = employees_df.dropna(axis = 0, how ='any')
employees_df_dropped
```

```
[16]:
```

	First Name	Gender	Start Date	Last Login Time	Salary	Bonus %	\

```

```
[903 rows x 8 columns]
```

Finally we compare the sizes of dataframes so that we learn how many rows had at least 1 Null value.

```
[17]: print("Old data frame length:", len(employees_df))
      print("New data frame length:", len(employees_df_dropped))
      print("Number of rows with at least 1 NaN value: ",
            (len(employees_df)-len(employees_df_dropped)))
```

```
Old data frame length: 1004
```

```
New data frame length: 903
```

```
Number of rows with at least 1 NaN value: 101
```

4.4.2 Find and remove duplicates in dataset

This section was inspired by: - [How to Find Duplicates in Pandas DataFrame \(With Examples\)](#) - [How to Drop Duplicate Rows in a Pandas DataFrame](#)

Checking for duplicate values using duplicated() In order to check for duplicate values in Pandas DataFrame, we use a function `duplicated()`. This function can be used in two ways: - find duplicate rows across **all columns** with `duplicateRows = df[df.duplicated()]` - find duplicate rows across **specific columns** `duplicateRows = df[df.duplicated(subset=['col1', 'col2'])]`

Find duplicate rows across **all columns**:

```
[18]: # import (again) data to dataframe from csv file
      employees_df = pd.read_csv("../datasets/employees_edit.csv")
```

```
[19]: # find duplicate rows across all columns
      duplicateRows = employees_df[employees_df.duplicated()]
      duplicateRows
```

```
[19]:
```

	First Name	Gender	Start Date	Last Login Time	Salary	Bonus %	\				
112	Karen	Female	11/30/1999	7:46 AM	102488	17653.0					
127	Linda	Female	5/25/2000	5:45 PM	119009	12506.0					
296	Brandon	NaN	11/3/1997	8:17 PM	121333	15295.0					
580	Nicholas	Male	3/1/2013	9:26 PM	101036	2826.0					
	Senior Management			Team							
112		True		Product							
127		True	Business Development								
296		False	Business Development								

580 True Human Resources

```
[20]: # argument keep='last' displays the first duplicate rows instead of the last
duplicateRows = employees_df[employees_df.duplicated(keep='last')]
duplicateRows
```

```
[20]:      First Name  Gender  Start Date  Last Login Time  Salary  Bonus %  \
55      Karen  Female  11/30/1999      7:46 AM  102488  17653.0
92      Linda  Female   5/25/2000      5:45 PM  119009  12506.0
153     Brandon   NaN   11/3/1997      8:17 PM  121333  15295.0
442    Nicholas   Male   3/1/2013      9:26 PM  101036   2826.0

      Senior Management      Team
55      True      Product
92      True  Business Development
153     False  Business Development
442      True   Human Resources
```

Find duplicate rows across **specific columns**:

```
[21]: # identify duplicate rows across 'First Name' and 'Last Login Time' columns
duplicateRows = employees_df[employees_df.duplicated(
    subset=['First Name', 'Last Login Time'])]
duplicateRows
```

```
[21]:      First Name  Gender  Start Date  Last Login Time  Salary  Bonus %  \
112      Karen  Female  11/30/1999      7:46 AM  102488  17653.0
127      Linda  Female   5/25/2000      5:45 PM  119009  12506.0
296     Brandon   NaN   11/3/1997      8:17 PM  121333  15295.0
577      NaN  Female   1/13/2009      1:01 PM  118736   7421.0
580    Nicholas   Male   3/1/2013      9:26 PM  101036   2826.0
632      NaN   NaN     9/2/1988     12:49 PM  147309   1702.0
881      NaN   Male     9/5/1980      7:36 AM  114896  13823.0

Dropping duplicate values using drop_duplicates() In order to drop duplicate values from a dataframe, we use drop_duplicates() function.

This function can be used in two ways: - remove duplicate rows across **all columns** with df.drop_duplicates() - find duplicate rows across **specific columns** df.drop_duplicates(subset=['col1', 'col2'])

Attention: We are doing that directly in this dataframe with inplace = True - we don't make a deep copy!

Remove duplicate rows across **all columns**:

```
[23]: # remove duplicate rows across all columns
employees_df.drop_duplicates(inplace=True)
employees_df
```

```
[23]:
```

	First Name	Gender	Start Date	Last Login Time	Salary	Bonus %	\

4.5 Avoidance of tendencies due to bias

The description of the Iris dataset says, that it consists of **50 samples** from **each of three species** of Iris (Iris setosa, Iris virginica and Iris versicolor), so there are **150 total samples**.

But how to prove it?

4.5.1 Count occurrences of unique values

To prove whether all possible classes included in the dataset and equally distributed, you can use the function `df.value_counts`.

Following parameters can be used for fine tuning: - `dropna=False` causes that NaN values are included - `normalize=True`: relative frequencies of the unique values are returned - `ascending=False`: sort resulting classes descending

```
[25]: # import (again) data to dataframe from csv file
employees_df = pd.read_csv("../datasets/employees_edit.csv")
```

```
[26]: # count unique values without missing values in a column,
# ordered descending and normalized
irisdata_df['species'].value_counts(ascending=False, dropna=False, normalize=True)
```

```
[26]: Iris-setosa          0.333333
Iris-versicolor         0.333333
Iris-virginica          0.333333
Name: species, dtype: float64
```

```
[27]: # count unique values and missing values in a column,
# ordered descending and not absolute values
employees_df['Team'].value_counts(ascending=False, dropna=False, normalize=False)
```

```
[27]: Client Services      106
Business Development     103
Finance                  102
Marketing                 98
Product                  96
Sales                    94
Engineering               92
Human Resources           92
Distribution              90
Legal                     88
NaN                       43
Name: Team, dtype: int64
```

4.5.2 Display Histogram

This section was inspired by: [Pandas Histogram – DataFrame.hist\(\)](#).

Histograms represent **frequency distributions** graphically. This requires the separation of the data into classes (so-called **bins**).

These classes are represented in the histogram as rectangles of equal or variable width. The height of each rectangle then represents the (relative or absolute) **frequency density**.

```
[28]: employees_df.hist(column=['Salary'])
plt.show()
```

Figure 4:

```
[29]: employees_df.hist(column='Salary', by='Gender')
plt.show()
```

4.6 First idea of correlations in data set

To get a rough idea of the **dependencies** and **correlations** in the data set, it can be helpful to visualize the whole dataset in a **correlation heatmap**. They show in a glance which variables are correlated, to what degree and in which direction.

Later, 2 particularly well correlated variables are selected from the data set and plotted in a **scatterplot**.

4.6.1 Visualise data with correlation heatmap

This section was inspired by [How to Create a Seaborn Correlation Heatmap in Python?](#).

Correlation matrices are an **essential tool of exploratory data analysis**. Correlation heatmaps contain the same information in a visually appealing way. What more: they show in a glance which variables are correlated, to what degree, in which direction, and alerts us to potential multicollinearity problems (source: ibidem).

Simple correlation matrix Because **string values can never be correlated**, the class names (species) have to be converted first:

```
[30]: # encoding the class column
irisdata_df_enc = irisdata_df.replace({"species": {"Iris-setosa":0,
```

Figure 5:

```
irisdata_df_enc["Iris-versicolor":1,
                "Iris-virginica":2}})
```

```
[30]:
```

	sepal_length	sepal_width	petal_length	petal_width	species
0	5.1	3.5	1.4	0.2	0
1	4.9	3.0	1.4	0.2	0
2	4.7	3.2	1.3	0.2	0
3	4.6	3.1	1.5	0.2	0
4	5.0	3.6	1.4	0.2	0
5	5.4	3.9	1.7	0.4	0
6	4.6	3.4	1.4	0.3	0
7	5.0	3.4	1.5	0.2	0
8	4.4	2.9	1.4	0.2	0
9	4.9	3.1	1.5	0.1	0

141	6.9	3.1	5.1	2.3	2

142	5.8	2.7	5.1	1.9	2
143	6.8	3.2	5.9	2.3	2
144	6.7	3.3	5.7	2.5	2
145	6.7	3.0	5.2	2.3	2
146	6.3	2.5	5.0	1.9	2
147	6.5	3.0	5.2	2.0	2
148	6.2	3.4	5.4	2.3	2
149	5.9	3.0	5.1	1.8	2

[150 rows x 5 columns]

```
[31]: irisdata_df_enc.corr()
```

```
[31]:
```

	sepal_length	sepal_width	petal_length	petal_width	species
sepal_length	1.000000	-0.109369	0.871754	0.817954	0.782561
sepal_width	-0.109369	1.000000	-0.420516	-0.356544	-0.419446
petal_length	0.871754	-0.420516	1.000000	0.962757	0.949043
petal_width	0.817954	-0.356544	0.962757	1.000000	0.956464
species	0.782561	-0.419446	0.949043	0.956464	1.000000

Correlation heatmap Choose the color sets from [color map](#).

```
[32]: # increase the size of the heatmap
plt.figure(figsize=(16, 6))

# store heatmap object in a variable to easily access it
# when you want to include more features (such as title)
# set the range of values to be displayed on the colormap from -1 to 1,
# and set 'annotation=True' to display the correlation values on the heatmap
heatmap = sns.heatmap(irisdata_df_enc.corr(), vmin=-1, vmax=1,
                      annot=True, cmap='PRGn_r')

# give a title to the heatmap
# 'pad=12' defines the distance of the title from the top of the heatmap
heatmap.set_title('Correlation Heatmap', fontdict={'fontsize':18}, pad=16)
plt.show()
```

Figure 6:

Triangle correlation heatmap When looking at the correlation heatmaps above, you would not lose any information by **cutting** away half of it **along the diagonal** line marked by 1-s.

The **numpy** function `np.triu()` can be used to isolate the upper triangle of a matrix while turning all the values in the lower triangle into 0.

```
[33]: import numpy as np

np.triu(np.ones_like(irisdata_df_enc.corr()))
```

```
[33]: array([[1., 1., 1., 1., 1.],
           [0., 1., 1., 1., 1.],
           [0., 0., 1., 1., 1.],
           [0., 0., 0., 1., 1.],
           [0., 0., 0., 0., 1.]])
```

Use this mask to cut the heatmap along the diagonal:

```
[34]: plt.figure(figsize=(16, 6))

# define the mask to set the values in the upper triangle to 'True'
mask = np.triu(np.ones_like(irisdata_df_enc.corr(), dtype=bool))

heatmap = sns.heatmap(irisdata_df_enc.corr(), mask=mask,
                      vmin=-1, vmax=1, annot=True, cmap='PRGn_r')

heatmap.set_title('Triangle Correlation Heatmap', fontdict={'fontsize':18}, pad=16)
plt.show()
```

Figure 7:

As a result from the **heatmaps** we can see, that the shape of the **petals** are the **most correlated columns** (0.96) with the **type of flowers** (species classes).

Somewhat lower correlates **sepal length** with **petal length** (0.87).

4.6.2 Visualise data with scatter plot

In the following, **Seaborn** is applied which is a library for making statistical graphics in Python. It is built on top of **matplotlib** and closely integrated with **pandas** data structures.

To investigate whether there are dependencies (e.g. correlations) in `irisdata_df` between individual variables in the data set, it is advisable to plot them in a **scatter plot**.

```
[69]: # There are five preset seaborn themes: darkgrid, whitegrid, dark, white, and ticks.
sns.set_style("whitegrid")
# set scale of fonts
sns.set_context("notebook", font_scale=1.3, rc={"lines.linewidth": 2.5})

# 'sepal_length', 'petal_length' are iris feature data
# 'height' used to define height of graph
# 'hue' stores the class/label of iris dataset
sns.FacetGrid(irisdata_df, hue="species",
               height=7).map(plt.scatter,
                             'petal_width',
                             'petal_length').add_legend()

plt.title('Scatterplot of petal length and width')
plt.show()
```

Figure 8:

4.6.3 Visualise data with pairs plot

For systematic investigation of dependencies, all variables (each against each) are plotted in separate scatter plots.

With this so called **pairs plot** it is possible to see both **relationships** between two variables and **distribution** of single variables.

This function will create a grid of Axes such that **each numeric variable** in `irisdata_df` will be shared in the y-axis across a single row and in the x-axis across a single column.

```
[36]: sns.set_style("white")
g = sns.pairplot(irisdata_df, diag_kind="kde", hue='species',
                palette='Dark2', height=2.5)

g.map_lower(sns.kdeplot, levels=4, color=".2")

plt.show()
```

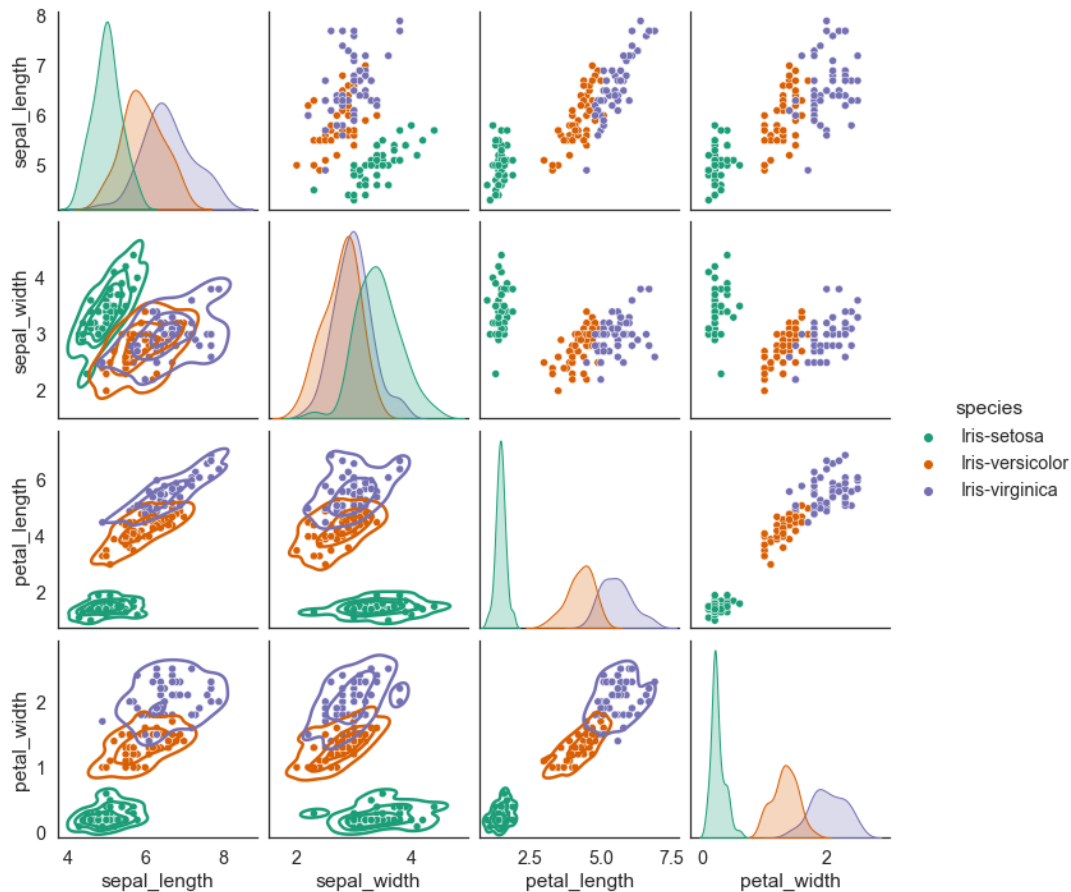

Figure 9:

5 STEP 2: Prepare the dataset

Through the intensive exploration of the data in Step 1 ([STEP 1: Exploring the dataset](#)), we know that special **preparation** of the data is **not necessary**. The values are **complete** and **without gaps** and there are **no duplicates**. The values are in similar ranges, which **does not require normalization** of the data.

Furthermore, we know that the **classes** are very **evenly distributed** and thus bias tendencies should be avoided.

6 STEP 3: Classify by support vector classifier - SVC

6.1 Operating principal

Support Vectors Classifier tries to **find the best hyperplane to separate** the different classes by maximizing the distance between sample points and the hyperplane (source: [In Depth: Parameter tuning for SVC](#)).

The figure ?? shows the operating principal of the SVC algorithm: the hyperplanes $H1$ till $H4$ (left graphic) do separate the classes. A good separation is achieved by the hyperplane that has the largest distance to the nearest training-data point of any class (so-called functional margin), since in general the larger the margin, the lower the generalization error of the classifier (source: [Support-vector machine](#)).

The right graphic shows the optimal hyperplane characterized by maximising the margin between the classes. The perpendicular distance of the closest data points to the hyperplane determines their position and orientation. These perpendicular distances are the **support vectors** of the hyperplane - this is how the algorithm got its name.

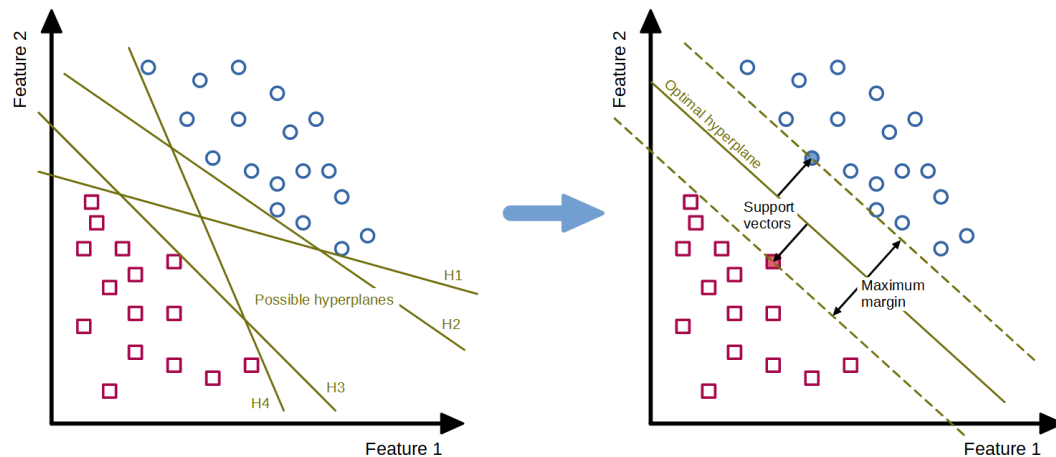

Figure 10: Support Vectors Classifiers (SVC) separate the data points in classes by finding the best hyperplane

6.2 Split the dataset

In the next very important step, the dataset is split into **2 subsets**: a **training dataset** and a **test dataset**. As the names suggest, the training dataset is used to train the ML algorithm. The test data set is then used to check the quality of the trained ML algorithm (here the **recognition rate**). For this purpose, the **class labels** are **removed** from the training data set - after all, these are to be predicted.

Typically, the **test dataset** should contain about **20%** of the entire dataset.

```
[52]: from sklearn.model_selection import train_test_split

X = irisdata_df.drop('species', axis=1)
y = irisdata_df['species']

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size = 0.20)
```

For training, do not use only the variables that correlate best with each other, but all of them.

Otherwise, the result of the prediction would be significantly worse. Maybe this is already an indication of **overfitting** of the ML model.

```
[38]: # DO NOT USE THIS!!
X_train, X_test, y_train, y_test = train_test_split(X[['sepal_length',
                                                         'sepal_width']],
                                                    y, test_size = 0.20)
```

6.3 Create the SVM model

In this step we create the SVC model and fit it to our training data.

```
[53]: from sklearn.svm import SVC
classifier = SVC(kernel = 'linear', random_state = 0)

# fit the model for the data
classifier.fit(X_train, y_train)
```

```
[53]: SVC(kernel='linear', random_state=0)
```

6.4 Make predictions

```
[54]: y_pred = classifier.predict(X_test)
#X_test
```

7 STEP 4: Evaluate the classification results - metrics

And finally for checking the accuracy of the model, the **confusion matrix** is used for the **cross validation**.

By using the function `sklearn.metrics.confusion_matrix()` a confusion matrix of the true digit values versus the predicted digit values is plotted.

7.1 Textual confusion matrix

```
[55]: cm = metrics.confusion_matrix(y_test, y_pred)
print(cm)
```

```
[[14  0  0]
 [ 0  9  1]
 [ 0  0  6]]
```

7.2 Colored confusion matrix

The function `sklearn.metrics.ConfusionMatrixDisplay()` plots a colored confusion matrix.

```
[67]: sns.set_style("white")

# print colored confusion matrix
cm_colored = metrics.ConfusionMatrixDisplay.from_predictions(y_test, y_pred)

#cm_colored.figure_.suptitle("Confusion Matrix")
cm_colored.figure_.set_figwidth(8)
cm_colored.figure_.set_figheight(7)

cm_colored.confusion_matrix

# save figure as PNG
plt.tight_layout()
plt.savefig('images/confusion_matrix.png', dpi=150, pad_inches=5)
plt.show()
```

```
[43]: from sklearn.model_selection import cross_val_score

accuracies = cross_val_score(estimator = classifier, X = X_train,
                              y = y_train, cv = 10)
```

Figure 11:

```
print("Accuracy: {:.2f} %".format(accuracies.mean()*100))
print("Standard Deviation: {:.2f} %".format(accuracies.std()*100))
```

Accuracy: 79.17 %
Standard Deviation: 6.72 %

8 STEP 5: Select SVC kernel and vary parameters

This section was inspired by [In Depth: Parameter tuning for SVC](#)

In this section, the 4 SVC parameters `kernel`, `gamma`, `C` and `degree` will be introduced one by one. Furthermore, their influence on the classification result by varying these single parameters will be shown.

Disclaimer: In order to show the effects of varying the individual parameters in 2D graphs, only the best correlating variables `petal_length` and `petal_width` are used to train the SVC.

8.1 Prepare dataset

```
[44]: # import iris dataset again
irisdata_df = pd.read_csv('./datasets/IRIS_flower_dataset_kaggle.csv')

# encode the class column from class strings to integer equivalents
irisdata_df_enc = irisdata_df.replace({"species": {"Iris-setosa":0,
                                                    "Iris-versicolor":1,
```

```
irisdata_df_enc
```

```
[44]:
```

	sepal_length	sepal_width	petal_length	petal_width	species
0	5.1	3.5	1.4	0.2	0
1	4.9	3.0	1.4	0.2	0
2	4.7	3.2	1.3	0.2	0
3	4.6	3.1	1.5	0.2	0
4	5.0	3.6	1.4	0.2	0
5	5.4	3.9	1.7	0.4	0
6	4.6	3.4	1.4	0.3	0
7	5.0	3.4	1.5	0.2	0
8	4.4	2.9	1.4	0.2	0
9	4.9	3.1	1.5	0.1	0
10	5.4	3.7	1.5	0.2	0
11	4.8	3.4	1.6	0.2	0
12	4.8	3.0	1.4	0.1	0
13	4.3	3.0	1.1	0.1	0
14	5.8	4.0	1.2	0.2	0
..
135	7.7	3.0	6.1	2.3	2
136	6.3	3.4	5.6	2.4	2
137	6.4	3.1	5.5	1.8	2
138	6.0	3.0	4.8	1.8	2
139	6.9	3.1	5.4	2.1	2
140	6.7	3.1	5.6	2.4	2
141	6.9	3.1	5.1	2.3	2
142	5.8	2.7	5.1	1.9	2
143	6.8	3.2	5.9	2.3	2
144	6.7	3.3	5.7	2.5	2
145	6.7	3.0	5.2	2.3	2
146	6.3	2.5	5.0	1.9	2
147	6.5	3.0	5.2	2.0	2
148	6.2	3.4	5.4	2.3	2
149	5.9	3.0	5.1	1.8	2

```
[150 rows x 5 columns]
```

```
[45]: # copy only 2 feature columns
# and convert pandas dataframe to numpy array
X = irisdata_df_enc[['petal_length', 'petal_width']].to_numpy(copy=True)
#X = irisdata_df_enc[['sepal_length', 'sepal_width']].to_numpy(copy=True)
#X
```

```
[46]: # convert pandas dataframe to numpy array
# and get a flat 1D copy of 2D numpy array
y = irisdata_df_enc[['species']].to_numpy(copy=True).flatten()
#y
```

8.2 Plotting function

This function helps to visualize the modifications by varying the individual SVC parameters.

```
[47]: def plotSVC(title, xlabel, ylabel):
# create a mesh to plot in
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
```

```

y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1

# prevent division by zero
if x_min == 0.0:
    x_min = 0.1

h = (x_max / x_min)/1000
xx, yy = np.meshgrid(np.arange(x_min, x_max, h), np.arange(y_min, y_max, h))

plt.subplot(1, 1, 1)
Z = svc.predict(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.contourf(xx, yy, Z, cmap=plt.cm.Paired, alpha=0.6)
plt.scatter(X[:, 0], X[:, 1], c=y, cmap=plt.cm.Paired)
plt.xlabel(xlabel)
plt.ylabel(ylabel)
plt.xlim(xx.min(), xx.max())
plt.title(title)
plt.show()

```

8.3 Vary kernel parameter

The **kernel** parameter selects the type of hyperplane that is used to separate the data. Using **linear** ([linear classifier](#)) kernel will use a linear hyperplane (a line in the case of 2D data). The **rbf** ([radial basis function kernel](#)) and **poly** ([polynomial kernel](#)) kernel use non linear hyperplanes.

```

[48]: kernels = ['linear', 'rbf', 'poly']

xlabel = 'Petal length'
ylabel = 'Petal width'

for kernel in kernels:
    svc = svm.SVC(kernel=kernel).fit(X, y)
    plotSVC('kernel = ' + str(kernel), xlabel, ylabel)

```

8.4 Vary gamma parameter

The **gamma** parameter is used for non linear hyperplanes. The higher the **gamma** value it tries to exactly fit the training data set.

As we can see, increasing **gamma** leads to **overfitting** as the classifier tries to perfectly fit the training data.

```

[49]: gammas = [0.1, 1, 10, 100, 200]

xlabel = 'Petal length'
ylabel = 'Petal width'

for gamma in gammas:
    svc = svm.SVC(kernel='rbf', gamma=gamma).fit(X, y)
    plotSVC('gamma = ' + str(gamma), xlabel, ylabel)

```

Figure 12:

Figure 13:

Figure 14:

Figure 15:

8.5 Vary C parameter

The C parameter is the **penalty** of the error term. It controls the trade off between smooth decision boundary and classifying the training points correctly.

Figure 16:

Figure 17:

But be careful: too high C values may lead to **overfitting** the training data.

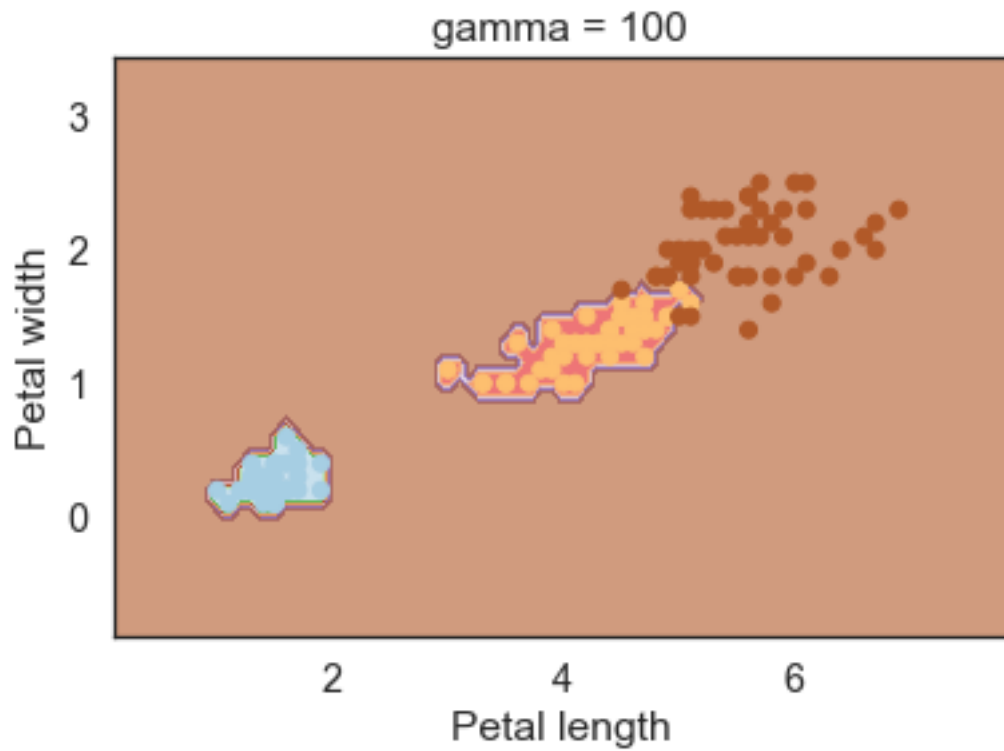

Figure 18:

Figure 19:

```
[50]: cs = [0.1, 1, 10, 100, 1000, 10000]
```

```

xlabel = 'Petal length'
ylabel = 'Petal width'

for c in cs:
    svc = svm.SVC(kernel='rbf', C=c).fit(X, y)
    plotSVC('C = ' + str(c), xlabel, ylabel)

```

Figure 20:

8.6 Vary degree parameter

The `degree` parameter is used when the `kernel` is set to `poly`. It's basically the **degree of the polynomial** used to find the hyperplane to split the data.

Using `degree = 1` is the same as using a `linear` kernel. Also, increasing this parameters leads to **higher training times**.

```

[51]: degrees = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

xlabel = 'Petal length'
ylabel = 'Petal width'

for degree in degrees:
    svc = svm.SVC(kernel='poly', degree=degree).fit(X, y)
    plotSVC('degree = ' + str(degree), xlabel, ylabel)

```
